# Core Java 8 and Development Tools

Lesson 04: Classes and Objects

## Lesson Objectives

### After completing this lesson, participants will be able to:

- Define classes and objects
- Create Packages
- Work with Access Specifiers
- Define Constructors
- understand this reference
- Understand memory management in java
- use static keyword
- Declaring and using Enum
- Best Practices

## 4.1: Classes and Objects

## Classes and Objects

### Class:

- A template for multiple objects with similar features
- A blueprint or the definition of objects

### Object:

- Instance of a class
- Concrete representation of class

```
class < class_name>
{
    type var1; ...
    Type method_name(arguments)
    {
       body
      } ...
} //class ends
```

## 4.1: Classes and Objects

### Introduction to Classes

- Fields
- Methods
- Constructors
- Initializers

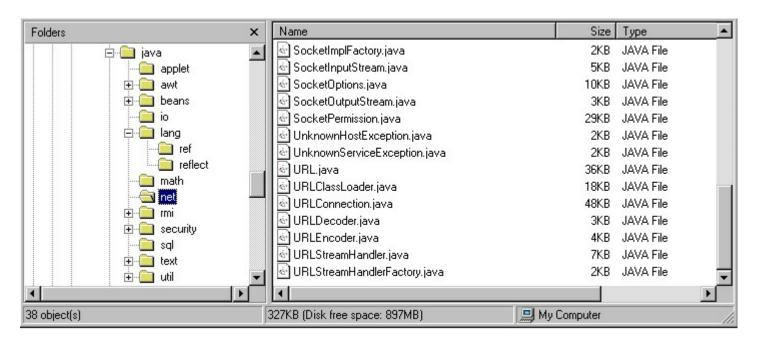

## **4.1 : Classes and Objects**Introduction to Classes

## 4.2: Packages Packages

In Java, by the use of packages, you can group a number of related classes and/or interfaces together into a single unit.

## 4.2: Packages Benefits of Packages

These are the benefits of organising classes into packages:

- It prevents name-space collision.
- It indicates that the classes and interfaces in the package are related.
- You know where to find the classes you want if they're in a specific package.
- It is convenient for organizing your work and separating your work from code libraries provided by others.

## 4.2: Packages Creating Your Own Package

```
package com.igate.trg.demo;
public class Balance {
    String name;
    public Balance(String n) {
        name = n;
    }
    public void show() {
        .....
        if( bal < 0)
            System.out.println(name + ": $" + bal);
}</pre>
```

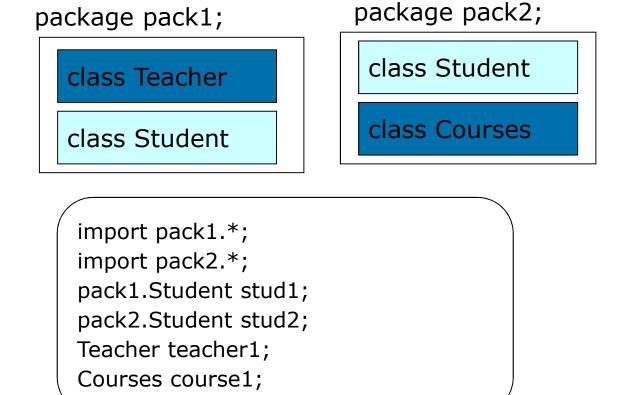

Package should be the first statement

## 4.2: Packages Packages and Name Space Collision

Namespace collision can be avoided by accessing classes with the same name in multiple packages by their fully qualified name.

## 4.2: Packages Using Packages

```
Use fully qualified name.
     java.util.Date = new java.util.Date();
You can use import to instruct Java where to look for things defined outside
your program.
                                                            You can use
                                                            multiple
     import java.util.Scanner;
                                                            import
     Scanner sc = new Scanner (System.in);
                                                            statements
You can use * to import all classes in package:
                                                               Use * carefully;
     import java.util.*;
                                                               you may
                                                               overwrite
     Scanner sc = new Scanner (System.in);
                                                               definitions
```

Static import enables programmers to import static members.

Class name and a dot (.) are not required to use an imported static member.

## 4.2: Packages Some Java Packages

| Package<br>Name | Description   |  |
|-----------------|---|--|
| java.lang       | Classes that apply to the language itself, which includes the Object class, the String class, and the System class. It also contains the Wrapper classes. "Classes belonging to java.lang package need not be explicitly imported". |  |
| java.util       | Utility classes, such as Date, as well as collection classes, such as Vector and Hashtable  |  |
| java.io         | Input & output classes for writing to & reading from streams (such as standard input and output) & for handling files   |  |
| java.net        | Classes for networking support, including Socket and URL (a class to represent references to documents on the WWW)  |  |
| java.applet     | Classes to implement Java applets, including the Applet class itself, as well as the AudioClip interface  |  |

## 4.2: Packages Demo: Package

### Execute the following programs:

- Balance.java
- AccountBalance.java
- StaticImportDemo.java
- StaticImportNotUsed.java

## **4.3: Access Modifiers**Types of Access Modifiers

Default

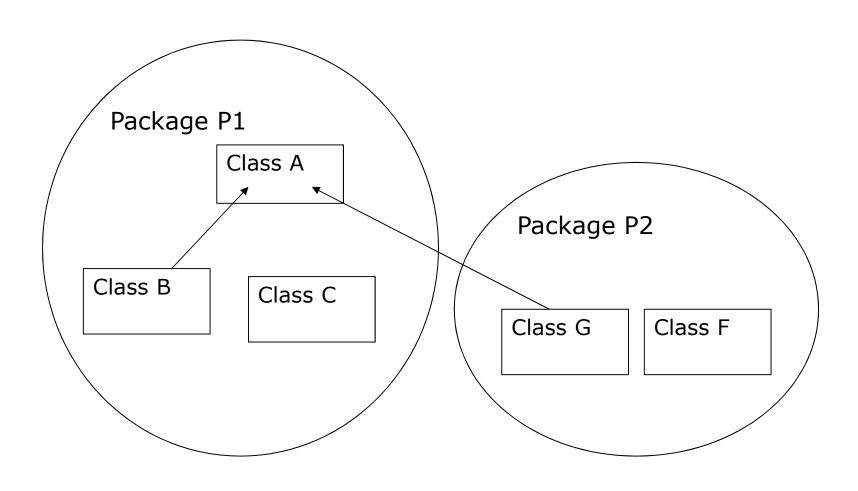

Private

**Public** 

Protected

| Location/Access<br>Modifier        | Privat<br>e | Defau<br>It | Protect<br>ed | Publi<br>c |
|------------------------------------|-------------|-------------|---------------|------------|
| Same class                         | Yes         | Yes         | Yes           | Yes        |
| Same package subclass              | No          | Yes         | Yes           | Yes        |
| Same package non-<br>subclass      | No          | Yes         | Yes           | Yes        |
| Different package subclass         | No          | No          | Yes           | Yes        |
| Different package non-<br>subclass | No          | No          | No            | Yes        |

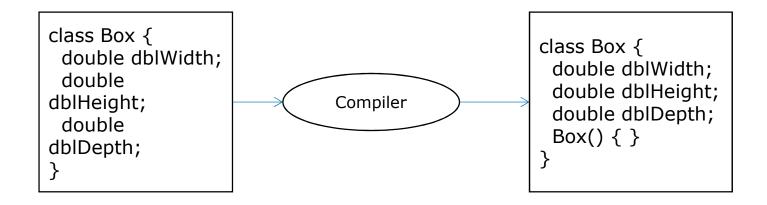

## 4.3: Access Specifiers and Modifiers What is access protection?

## **4.4: Constructors**Default Constructors

### All Java classes have constructors

- Constructors initialize a new object of that type
   Default no-argument constructor is provided if program has no constructors
   Constructors:
- Same name as the class
- No return type, not even void

## **4.4: Constructors**Demo

Execute the BoxDemo.java program.

This uses the Box.java

## 4.5: this reference this reference

The this keyword is used to refer to the current object from any method or constructor.

There are mainly two uses of this keyword:

- Refer the class level fields
- Chaining constructors

```
// Field reference using this
class Point {
    int xCord;// instance variable
    int yCord;

    Point(int xCord, int yCord) {
        this.xCord = xCord;
        this.yCord = yCord;
    }
}
```

## 4.6: Memory Management Memory Management

Dynamic and Automatic

No *Delete* operator

Java Virtual Machine (JVM) de-allocates memory allocated to unreferenced objects during the garbage collection process

## 4.6: Memory Management Enhancement in Garbage Collector

### Garbage Collector:

- Lowest Priority Daemon Thread
- Runs in the background when JVM starts
- Collects all the unreferenced objects
- Frees the space occupied by these objects
- Call System.gc() method to "hint" the JVM to invoke the garbage collector
  - There is no guarantee that it would be invoked. It is implementation dependent

## 4.6: Memory Management Finalize() Method

Memory is automatically de-allocated in Java

Invoke *finalize()* to perform some housekeeping tasks before an object is garbage collected

Invoked just before the garbage collector runs:

protected void finalize()

## 4.7: using static keyword Static modifier

Static modifier can be used in conjunction with:

- A variable
- A method

Static members can be accessed before an object of a class is created, by using the class name

### Static variable:

- Is shared by all the class members
- Used independently of objects of that class
- Example: static int intMinBalance = 500;

## 4.7: using static keyword

### Static modifier

### Static methods:

- Can only call other static methods
- Must only access other static data
- Cannot refer to this or super in any way
- Cannot access non-static variables and methods

### Static constructor:

used to initialize static variables

Method main() is a static method. It is called by JVM.

## 4.7: using static keyword

Static modifier

```
// Demonstrate static variables, methods, and blocks.
public class UseStatic {
  static int intNum1 = 3;
                                            // static variable
  static int intNum2;
                                    //static constructor
static {
       System.out.println("Static block initialized.");
       intNum2 = intNum1 * 4;
  static void myMethod(int intNum3) { // static method
        System.out.println("Number3 = " + intNum3);
        System.out.println("Number1 = " + intNum1);
        System.out.println("Number2 = " + int
                                                  Output:
                                                  Static block initialized
public static void main(String args[]) {
                                                  Number3 = 42
                                                  Number1 = 3
  myMethod(42);
                                                  Number2 = 12
  }}
```

## 4.8: Enums Enums

## ENUM representation pre-J2SE 5.0

public static final int SEASON\_WINTER = 0; public static final int SEASON\_SUMMER = 1; public static final int SEASON\_SUMMER = 2;

### Problem?

- Not type safe (any integer will pass)
- No namespace (SEASON\_\*)
- Brittleness (how do add value in-between?)
- Printed values uninformative (prints just int values)

Solution: New type of class declaration

enum type has public, self-typed members for each enum constant

## **4.8: Enums**Declaring Type Safe Enums

Permits variable to have only a few pre-defined values from a given list Helps reduce bugs in the code

• Example:

enum CoffeeSize { BIG, HUGE, OVERWHELMING };
CoffeeSize cs = CoffeeSize.BIG;
cs can have values BIG, HUGE and OVERWHELMING only

### 4.8: Enums

### Enums with Constructors, Methods and Variables

Add constructors, instance variables, methods, and a constant specific class body

• Example:

```
enum CoffeeSize {
    BIG(8), HUGE(10), OVERWHELMING(16);
    // the arguments after the enum value are "passed"
    // as values to the constructor
    CoffeeSize(int ounces) {
        this.ounces = ounces;
        // assign the value to an instance variable
}
```

## 4.8: Enums Demo

Demo: EnumMonths.java

## **4.9: Best Practices**Constructor

Initializing fields to default values is redundant Constructors should not call *overridables* Beware of mistaken field *redeclares* 

```
public final class Quark {
   //private String fName;
   //private double fMass;
   public Quark(String aName, double aMass){
        fName = aName;
        fMass = aMass;
      }
   //WITH redundant initialization to default values
   private String fName = null;
   private double fMass = 0;
}
>javap -c -classpath . Quark
```

## 4.9: Best Practices Static and Constants

Declare constants as static and final Static, final and private methods are faster If possible, use constants in *if* conditions

## Lab

Lab 2: Language Fundamentals , Classes and Objects

### Summary

### In this lesson you have learnt:

- Classes and Objects
- Packages
- Access Specifiers
- Constructors Default and Parameterized
- this reference
- Memory management
- Using static keyword
- Enums
- Best Practices

### **Review Questions**

Question 1: Which of the following are the benefits of using Package?

- Option1: prevents name-space collision.
- Option2: To implement security of contained classes.
- Option3: Better code library management.
- Option4: To increase performance of your class.

Question 2: Which of the following is true regarding enum?

- Option1: enum cannot be used inside methods.
- Option2: enum need not have a semicolon at the end.
- Option3: enum can be only declared with public or default access specifier.
- Option4: All the above are true.
